STRUCTURAL DYNAMIC DISCRETE CHOICE MODELS WITH FIXED EFFECTS

LECTURE 6

Econometric Society Summer School in Dynamic Structural Econometrics

Victor Aguirregabiria (University of Toronto)

UCL – July 1st, 2025

INTRODUCTION

- Disentangling true dynamics (causal effect of past decisions) versus spurious dynamics (persistent unobserved heterogeneity [UH] is a fundamental problem in the econometrics of dynamic models.
- Challenges with short panels (Heckman, 1981):
 - Incidental Parameters Problem (IPP): Treating UH as fixed parameters implies inconsistent estimation of parameters of interest.
 - Initial Conditions Problem (ICP): There is no Nonparametric Identification of the distribution of UH and initial conditions.
- Two alternative approaches to deal with the Nonparametric No-Identification from the ICP:
 - Random Effects (RE).
 - Fixed Effects (FE).

RANDOM EFFECTS (RE) vs. FIXED EFFECTS

- Random Effects (RE): Integrating out UH.
 - We deal with the ICP by imposing parametric & finite support restrictions on the joint distribution of UH and initial conditions.
 - Pros: Full identification of structural parameters & distribution of UH.
 - **Cons:** Misspecification of parametric restrictions on UH can introduce substantial biases in the estimates of "true dynamics".
- Fixed Effects (FE): Differencing out UH.
 - Focus on identification of structural parameters capturing "true dynamics" and not on the identification of the distrribution of UH.
 - Pros: NP specification of UH. Robust identification of true dynamics.
 - **Cons:** Distribution of UH is not fully identified. It limits the counterfactuals we can identify.
 - Cons: Not all dynamic models have consistent FE estimators.

FIXED EFFECTS IN STRUCTURAL DDC MODELS

- Until recently, all applications of Structual DDC models use RE models to deal with UH.
- The absence of applications using a FE approach was partly because of two common beliefs.
- Belief that there are not consistent FE estimators in structural models where agents are forward-looking: problem with continuation values.
- Belief that, even if structural parameters are identified, we cannot identify Average Marginal Effects (AME) and other Counterfactuals as these depend on the distribution of the UH.
 - Recent developments have challenged these beliefs.

BYPRODUCT OF FE APPROACH: COMPUTATIONAL GAINS

- As we will see, the application of the FE approach to dynamic structural models requires differencing out the continuation value component of the conditional choice value function.
- This implies that this estimation approach (Conditional MLE) does not require solving any dynamic programming problem, or computing present values, or even one-period forward expectation.
- The computational cost of implementing the Conditional MLE does not depend on the dimension of the state space.

THIS LECTURE

- This lecture presents recent results on Structural DDC FE Models.
- Aguirregabiria, Gu, & Luo (Journal of Econometrics, 2021)
 - Identification & estimation of structural DDC-FE with lagged decision and duration as state variables.
- Aguirregabiria (Econometrics Journal, 2023)
 - Application to dynamic demand for differentiated products
- This approach benefits from recent developments on the identification of nonlinear FE models: Bonhomme (ECMA, 2012), Chernozhukov et al. (ECMA, 2013), Honore & Weidner (2020) Aguirregabiria & Carro (2023), Patel & Weidner (2024).

OUTLINE

- 1. Model
- 2. Identification of Structural Parameters.
- 3. Conditional MLE of Structural Parameters.
- 4. Empirical application Dynamic Demand for Differentiated Product.

1. MODEL

MODEL: DECISION & STATE VARIABLES

- Decision variable: $y_{it} \in \mathcal{Y} = \{0, 1, ..., J\}.$
- Agent maximizes $\mathbb{E}_t \left[\sum_{s=0}^{\infty} \delta_i^s \ U_{i,t+s} \right]$. U_{it} is the utility function.
- U_{it} depends on current choice, y_{it} , and on:
- Two types of unobservables for the researcher, $(\alpha_i, \varepsilon_{it})$;
- Two types of observable state variables:

$$s_{it} = (z_{it}, x_{it})$$

 $z_{it} = \text{strictly exogenous state variables}.$

 $\mathbf{x}_{it} = \text{endogenous state variables}.$

MODEL: UTILITY FUNCTION

• The current payoff of choosing alternative *j*:

$$U_{it}(j) = \alpha_i(j) + \varepsilon_{it}(j) + \beta(j, \mathbf{s}_{it})$$

- Payoff function $\beta(j, \mathbf{s}_{it})$ is unrestricted.
- Unobservables:
 - Both types of onobservables are additively separable.
 - $\varepsilon_{it}(j)$ i.i.d. type I extreme value distributed;
 - **FE model**: $p(\alpha_i(0), ..., \alpha_i(J) \mid x_{i1}, z_{i1}, ..., z_{iT})$ is unrestricted.

OPTIMAL DECISION & CCPs (conditional on α_i)

• The optimal decision is:

$$y_{it} = \arg\max_{j \in \mathcal{Y}} \left\{ \alpha_i\left(j\right) + \varepsilon_{it}(j) + \beta\left(j, \boldsymbol{s}_{it}\right) + cv(j, \boldsymbol{s}_{it}, \boldsymbol{\alpha}_i) \right\}$$

• where $cv(j, \mathbf{s}_{it}, \mathbf{\alpha}_i)$ is the **continuation value function**:

$$cv(j, \mathbf{s}_{it}, \mathbf{\alpha}_i) \equiv \delta_i \int V(\mathbf{s}_{i,t+1}, \mathbf{\alpha}_i) f(\mathbf{s}_{i,t+1} \mid j, \mathbf{s}_{it}) d\mathbf{s}_{i,t+1}$$

• The extreme value type 1 distribution of the unobservables ε , implies the **conditional choice probability (CCP)** function:

$$P(j|\mathbf{s}_{it}, \alpha_i) = \frac{\exp \left\{\alpha_i(j) + \beta(j, \mathbf{s}_{it}) + cv(j, \mathbf{s}_{it}, \alpha_i)\right\}}{\sum\limits_{k \in \mathcal{Y}} \exp \left\{\alpha_i(k) + \beta(k, \mathbf{s}_{it}) + cv(k, \mathbf{s}_{it}, \alpha_i)\right\}}$$

2. IDENTIFICATION OF STRUCTURAL PARAMETERS

A RESTRICTED VERSION OF THE MODEL

- For simplicity, in this lecture I focus on identification results for a version of the model that imposes two additional restrictions.
- R1: No exogenous state variables z_{it}.
- R2: Endogenous state variables follow a deterministic transition rule:

$$\mathbf{x}_{i,t+1} = f(y_{it}, \mathbf{x}_{it})$$

- These restrictions have two important implications.
 - 1. The initial condition + choice path $\tilde{\mathbf{y}}_i = \{\mathbf{x}_{i1}, y_{i1}, y_{i2}, ..., y_{iT}\}$ contains all the information on the path of choices and states.
 - 2. For two pairs of choices and states, (j, \mathbf{x}) and (j', \mathbf{x}') , with $f(j, \mathbf{x}) = f(j', \mathbf{x}')$, their continuation values are also the same.

FE – SUFFICIENT STATISTICS APPROACH

• Let $\widetilde{\mathbf{y}} = \{\mathbf{x}_1, y_1, y_2, ..., y_T\}$ be an individual's observed history

$$\mathbb{P}\left(\widetilde{\boldsymbol{y}}|\boldsymbol{\alpha}\right) = \prod_{t=1}^{T} \frac{\exp\left\{\alpha\left(y_{t}\right) + \beta\left(y_{t}, \boldsymbol{x}_{t}\right) + v\left(f\left(y_{t}, \boldsymbol{x}_{t}\right), \boldsymbol{\alpha}\right)\right\}}{\sum\limits_{j \in \mathcal{Y}} \exp\left\{\alpha\left(j\right) + \beta\left(j, \boldsymbol{x}_{t}\right) + v\left(f\left(j, \boldsymbol{x}_{t}\right), \boldsymbol{\alpha}\right)\right\}} \rho(\boldsymbol{x}_{1}|\boldsymbol{\alpha})$$

The log-probability of a choice history has the following form:

$$\ln \mathbb{P}\left(\widetilde{\boldsymbol{y}}|\boldsymbol{\alpha}\right) = S(\widetilde{\boldsymbol{y}})' \ g(\boldsymbol{\alpha}) + C(\widetilde{\boldsymbol{y}})' \ \boldsymbol{\beta}$$

where $S(\widetilde{\mathbf{y}})$ and $C(\widetilde{\mathbf{y}})$ are vectors of statistics.

- For instance:

 - $\sum_{t=1}^{T} 1\{y_t = j\}$ is in $S(\widetilde{\mathbf{y}})$. $\sum_{t=2}^{T} 1\{y_{t-1} = k \text{ and } y_t = j\}$ is in $C(\widetilde{\mathbf{y}})$.

FE - SUFFICIENT STATISTICS APPROACH (2)

• This structure has several important implications.

$$\ln \mathbb{P}\left(\widetilde{\boldsymbol{y}}|\boldsymbol{\alpha}\right) = S(\widetilde{\boldsymbol{y}})' \ g(\boldsymbol{\alpha}) + C(\widetilde{\boldsymbol{y}})' \ \boldsymbol{\beta}$$

1. $S(\widetilde{\mathbf{y}})$ is a sufficient statistic for α .

$$\mathbb{P}\left(\widetilde{\boldsymbol{y}}\mid\boldsymbol{\alpha},S(\widetilde{\boldsymbol{y}})\right)=\mathbb{P}\left(\widetilde{\boldsymbol{y}}\mid S(\widetilde{\boldsymbol{y}})\right)$$

2. β is identified if conditional on $S(\widetilde{\boldsymbol{y}})$ the matrix $C(\widetilde{\boldsymbol{y}})'$ for every \boldsymbol{y} is full-column rank.

A MORE INTUITIVE DESCRIPTION OF IDENTIFICATION

- Suppose that there are two choice histories, say A and B For every parameter in the vector β , say β_k , there exist two choice histories, say $\widetilde{\mathbf{y}} = A$ and $\widetilde{\mathbf{y}} = B$ such that:
 - S(A) = S(B)
 - C(A) C(B) is a vector where all the elements are zero except for the element associated with β_k , which is $C_k \neq 0$.
- Under these conditions, we have that:

$$\beta_k = \frac{\log \mathbb{P}(A) - \log \mathbb{P}(B)}{C_k}$$

• Parameter β_k is identified from the log-odds-ratio of histories A & B.

THE CHALLENGE OF THE CONTINUATION VALUES

- The question is whether such histories A & B exist, or on the contrary, S(A) = S(B) implies that there is no variation left in $C(\widetilde{y})$.
- The continuation value $cv(f(y_t, \mathbf{x}_t), \boldsymbol{\alpha}_i)$ depends on $\boldsymbol{\alpha}_i$ in a nonlinear (and unknown) form.
- To difference out/control for α_i , we need to difference out the whole continuation value.
- But the continuation value also depends on the state variables. So, it seems that differencing out continuation values implies controlling for all the variation in the state variables: there is no variation left to identify the structural parameters β .
- Or there is?

DIFFERENCING OUT CONTINUATION VALUES

- It turns out that there is a broad and important class of dynamic models where we can difference out continuation values leaving variation in the state variables to identify structural parameters
- Remember that:

$$v(j, \mathbf{x}_t, \boldsymbol{\alpha}) = \alpha(j) + \beta(j, \mathbf{x}_t) + cv(f(j, \mathbf{x}_t), \boldsymbol{\alpha})$$

• Suppose that the transition rule f(.) is such that there exist two combinations of choice-state (y_t, \mathbf{x}_t) such that \mathbf{x}_{t+1} is the same:

$$f(j, \mathbf{x}) = f(j', \mathbf{x}')$$

Then, it is clear that:

$$v(j, \mathbf{x}, \alpha) - v(j', \mathbf{x}', \alpha) = \beta(j, \mathbf{x}) - \beta(j', \mathbf{x}')$$

• Under this condition, we can identify structural parameters β using a FE – Sufficient Statistics method.

EXAMPLE 1: MULTI-ARMED BANDIT MODELS

• In these models $x_t = y_{t-1}$ such that:

$$\mathbf{x}_{t+1} = f(y_t, \mathbf{x}_t) = f(y_t, y_{t-1}) = y_t$$

• Therefore, $cv(f(j, y_{t-1}), \alpha)$ does not depend on y_{t-1} .

$$v(j, y_{t-1}, \boldsymbol{\alpha}) = \alpha(j) + \beta(j, y_{t-1}) + cv(j, \boldsymbol{\alpha})$$

- The continuation values $cv(j, \alpha)$ are similar as the terms $\alpha(j)$ in the current utility: they do not interact with the state variable y_{t-1} .
- Switching cost parameters, $\beta(y_t, y_{t-1})$ are identified if $T \geq 4$.
- For instance, given choice histories A = (j, k, j, k) and B = (j, j, k, k), we have that:

$$\beta(j,k) = \log \mathbb{P}(A) - \log \mathbb{P}(B)$$

EXAMPLE 2: INVESTMENT MODELS

• In these models $y_t \in \{0, 1, 2, ...\}$ is the investment decision and x_t is the capital stock variable:

$$x_{t+1} = f(y_t, x_t) = x_t + y_t$$

• For any two values of the state, say x and x', we have that:

$$\begin{split} & \left[v(1,x,\alpha) - v(0,x+1,\alpha) \right] - \left[v(1,x',\alpha) - v(0,x'+1,\alpha) \right] \\ & = \left[\beta(1,x) - \beta(0,x+1) \right] - \left[\beta(1,x') - \beta(0,x'+1) \right] \end{split}$$

• Taking into account this structure, it is possible to construct pairs of choice histories, A and B, that identify parameters in β

3. ESTIMATION OF STRUCTURAL PARAMETERS

CONDITIONAL MAXIMUM LIKELIHOOD ESTIMATOR

• Remember that the probability of a choice history $\widetilde{\mathbf{y}}_i$ has the following structure:

$$\ln \mathbb{P}\left(\widetilde{\boldsymbol{y}}_{i} \middle| \boldsymbol{\alpha}_{i}\right) = S(\widetilde{\boldsymbol{y}}_{i})' \ g(\boldsymbol{\alpha}_{i}) + C(\widetilde{\boldsymbol{y}}_{i})' \ \boldsymbol{\beta}$$

and that $S(\widetilde{y}_i)$ is a sufficient statistic for α_i .

ullet We estimate $oldsymbol{eta}$ by maximizing the Conditional Likelihood function:

$$\ell^{C}(\boldsymbol{\beta}) = \sum_{i=1}^{N} \log \mathbb{P}\left(\widetilde{\boldsymbol{y}}_{i} \mid S(\widetilde{\boldsymbol{y}}_{i}), \boldsymbol{\beta}\right)$$

which has the following form:

$$\ell^{C}(\boldsymbol{\beta}) = \sum_{i=1}^{N} C(\widetilde{\boldsymbol{y}}_{i})' \boldsymbol{\beta} - \sum_{i=1}^{N} \ln \left[\sum_{\widetilde{\boldsymbol{y}} \ S(\widetilde{\boldsymbol{y}}) = S(\widetilde{\boldsymbol{y}}_{i})} \exp \left\{ C(\widetilde{\boldsymbol{y}})' \boldsymbol{\beta} \right\} \right]$$

CONDITIONAL MAXIMUM LIKELIHOOD ESTIMATOR (2)

$$\ell^{C}(\boldsymbol{\beta}) = \sum_{i=1}^{N} C(\widetilde{\boldsymbol{y}}_{i})' \boldsymbol{\beta} - \sum_{i=1}^{N} \ln \left[\sum_{\widetilde{\boldsymbol{y}} \ S(\widetilde{\boldsymbol{y}}) = S(\widetilde{\boldsymbol{y}}_{i})} \exp \left\{ C(\widetilde{\boldsymbol{y}})' \boldsymbol{\beta} \right\} \right]$$

- This Conditional Likelihood Function has several important properties:
- 1. It does not depend on the incidental parameters α .
- 2. It is globally concave in β .
- 3. The continuation values enter only in $g(\alpha_i)$. Controlling for **S** implies removing the continuation values.
- 4. Therefore, the computational cost of the Conditional MLE does not depend on the dimension of the state space.

4. EMPIRICAL APPLICATION

Dynamic Demand for Differentiated Product

Laundry Detergent

DATA

- NIELSEN scanner data from Chicago-Kilts center.
- Period 2006-2019. Current estimates using only years 2017-2018.
- More than 40k participating households all over US.
- Rich demographics (\mathbf{w}_i) : ZIP code, income, age, education, occupation, race, family size, family composition, type of residence,
- Data on every shopping trip.
- Product: Laundry detergent

ESTIMATION OF DEMAND PARAMETERS

Fixed Effects provide precise enough estimates (N = 19,776).

EXTENSIONS

- This paper presents a Fixed Effects dynamic panel data model of demand for different products where consumers are forward looking.
- Some relevant extensions:
- 1. Identification of aggregate price elasticities following Aguirregabiria & Carro (2023) results on the identification of Average Marginal Effects.
- 2. Identification of FE Dynamic games in Aguirregabiria, Gu, and Mira (2022).
- 3. Introducing stochastic transitions in endogenous state variables.
- 4. Counterfactuals
